Daily Scholar Papers Report — 2026-06-29

[Download PDF]

Window covered: 2026-06-28 → 2026-06-29 (Google Scholar alerts + user-curated self-emails, last 24 h)

Executive Summary

A **zero-alert** day: the 24 h Scholar-alert query returned no new threads, and the user-curated self-email queue was also empty. No candidates entered Stage-1, no deep-reads were performed, and the preference layer — which currently has only one attribute clearing the $n \geq 2$ promotion/demotion threshold — was effectively idle for lack of input. The pipeline ran end-to-end cleanly; the empty result is the result.

Outstanding: 0 · **Keep:** 0 · **Borderline High-Priority:** 0

Highlighted Papers

No papers cleared Stage-1 today.

#	Title	Authors	Venue	Link
—	*(empty)*	—	—	—

Cross-Paper Synthesis

Held until the next non-empty day. With zero papers surviving Stage-2 deep-read, there is no cross-paper signal to surface. The empty result reflects the input window — not a Stage-1 filter outcome — so today's run carries no information about subfield saturation, venue distribution, or methodology trends.

Writing & Rationale Insights

- *True-empty vs filtered-empty.* Today is a *true-empty* day (the upstream Gmail query returned zero threads), distinct from a *filtered-empty* day where candidates arrived but all were Stage-1-skipped. The previous run (2026-06-28) was filtered-empty — two saturated-subfield Recommended hits were correctly skipped. Distinguishing the two matters when reading the recent-history shape of the digest: a true-empty day says nothing about the rubric, a filtered-empty day affirms it.

- *Window-scope reminder.* The newer_than:1d strict 24 h scope is intentional. Occasional 0-thread days are within distribution given the Scholar alert cadence (≈ 4–6 threads / 24 h on the May–June 2026 baseline). The next non-empty day will resume the standard Highlighted Papers + Cross-Paper Synthesis structure.
- *Preference layer is still warming.* Only one attribute (`venue::preprint`, n=2) currently clears the n ≥ 2 threshold required for promotion/demotion. Future ratings — especially per-author and per-topic — will let the preference layer override the unbiased rubric more often. Empty days produce no new ratings, so the layer warms only on days the digest actually emits papers.
