Daily Scholar Papers Report — 2026-07-18

[Download PDF](#)

Window covered: 2026-07-17 → 2026-07-18 (Google Scholar alerts + user-curated self-emails, last 24 h)

Executive Summary

A *quiet-inbox* day. Zero new Google Scholar alert threads and zero user-curated self-emails landed inside the 24 h window. The two most recent Scholar threads (Ellis & Lin's PoPETs 2026 anonymity-leakage study and Robben & Vanhoef's ESORICS 2026 WireGuard security-testing paper) both carried 2026-07-16 16:16 UTC timestamps and were already fully deep-read in the [2026-07-17 digest](#). Nothing new has arrived since.

The preference posterior pipeline still ran: feedback pull found no open issues and the rebuild rewrote 19 attribute posteriors, with `venue::preprint` (0.75, $n = 2$) remaining the only $n \geq 2$ prior. The empty result is a genuine lull, not a connector failure — a control probe against `from:scholaralerts-noreply@google.com` without a date filter returned 201 historical threads, and the top result set matches the state observed on 2026-07-17.

Outstanding: 0 · **Keep:** 0 · **Borderline High-Priority:** 0

Highlighted Papers

No new papers reached Stage-2 deep-read today.

Cross-Paper Synthesis

Not applicable — no Stage-2 cohort to synthesise across. The next digest will resume the standard format once new alerts arrive.

Writing & Rationale Insights

A null-day is itself useful signal: it confirms that the scheduled task survives an empty inbox without producing fabricated content. Three operational invariants were exercised: (i) Stage-1 author-level exclusion remains armed and would have caught the 2026-07-14 Sun Yat-sen-adjacent *Sccodebert*

smart-contract paper had it fallen inside the window, (ii) STEP 2b parallel self-email channel is wired and returned 0 cleanly, and (iii) preference posteriors are refreshed even when no candidates are scored against them, so tomorrow's run starts from the latest n-of-history rather than a stale snapshot. Scholar's Recommended-articles cadence has historically clustered on 2-day intervals, so the next batch is most plausibly expected on the 2026-07-18 evening / 2026-07-19 morning UTC boundary — the next scheduled digest will pick it up.
