Daily Scholar Papers Report — 2026-07-30

[Download PDF](#)

Window covered: 2026-07-29 → 2026-07-30 (Google Scholar alerts + user-curated self-emails, last 24 h)

Executive Summary

No new candidates arrived in today's 24-hour window — the second consecutive quiet day. Both intake channels, Google Scholar alerts and the user-curated self-email queue, returned zero threads at run time. Each was re-queried in an absolute-date form, and the self-email channel was additionally re-queried without its `subject:` filter, to confirm the gap is real rather than an artefact of Gmail's rolling window or of an over-narrow query. No papers were screened at Stage-1 and none were deep-read.

There is no un-covered backlog behind the silence. The most recent Scholar batch landed on 2026-07-27 and was triaged in full by a previous run; the two self-curated papers still visible in a wider search date to the same morning and were deep-read in the 2026-07-27 digest. Report windows from 2026-07-26 onward abut one another with no gap, so nothing has fallen between runs. Carry-over from earlier days is not folded in, per the pipeline's rolling-window policy.

Outstanding: 0 · **Keep:** 0 · **Borderline High-Priority:** 0

Cross-Paper Synthesis

Not applicable — empty window.

Writing & Rationale Insights

Not applicable to today's intake, but the run itself is worth a line in the archive. The pipeline executed cleanly end to end: preference posteriors were refreshed (19 attributes on file, no new feedback issues open), the repository was already in sync, and every intake query reached the Gmail connector without error.

For anyone reading this archive as a time series, today marks the fifth quiet day of July and the first back-to-back pair of the month. The Scholar channel has been arriving in clusters separated by roughly one to three days of silence rather than on a daily cadence, so a zero-yield window reflects the delivery pattern of the source rather than any slowdown in the field. The practical lesson for a digest of this kind is that a negative result deserves the same evidentiary standard as a positive one: an empty report is only trustworthy if the emptiness was probed from more than one direction, which is why each channel here was checked against a second and, where the query carried filters that could themselves be the cause, a third formulation before the window was declared empty.
