Daily Scholar Papers Report — 2026-07-16

[Download PDF](#)

Window covered: 2026-07-15 → 2026-07-16 (Google Scholar alerts + user-curated self-emails, last 24 h)

Executive Summary

Empty window. No new Scholar-alert threads landed between the 2026-07-15 pipeline run and this morning, and the user-curated forward queue was also empty. The two Scholar-alert threads dated 2026-07-14 22:50 UTC were already ingested and reported yesterday. The preference layer stays quiet — the only attribute with $n \geq 2$ historical observations is `venue::preprint` (posterior 0.75, $n=2$), and there are no candidates for it to weigh in on. Feedback ingestion returned zero open issues; preference posteriors were nevertheless rebuilt so tomorrow's run starts fresh.

Outstanding: 0 · **Keep:** 0 · **Borderline High-Priority:** 0

Highlighted Papers

No papers cleared Stage-1 today — the 24-h window contained no new Scholar alerts and no user-curated forwards.

Cross-Paper Synthesis

Nothing new to synthesise today. The most recent themes still worth carrying forward from the 2026-07-15 batch are (i) two-channel, complementary embeddings as a design pattern for LLM-agent trajectory watermarks robust to both deletion and rewriting, and (ii) LLM-agent pipelines that reason over pseudocode-level diffs as a way to lift binary security-patch detection above shallow token statistics. Both remain open threads for future alerts.

Writing & Rationale Insights

An empty window is a useful reminder that the pipeline's default posture is quiet: no papers are surfaced when none arrive, rather than padding the report with lower-signal candidates from a wider search. The preference-posterior loop also matters most when candidates exist; on quiet days it simply refreshes so that the next non-empty run inherits an up-to-date `preferences.json`.
