Daily Scholar Papers Report — 2026-06-25

[Download PDF](#)

Window covered: 2026-06-24 → 2026-06-25 (Google Scholar alerts + user-curated self-emails, last 24 h)

Executive Summary

A *quiet-inbox* day. Zero new Google Scholar alert threads and zero user-curated self-emails landed inside the 24 h window. The three most recent Scholar threads (Vechev's TIGER on gradient inversion, the Zibaeirad–Vieira *Calibration Without Comprehension* CWE-Top-1 study, and the Zhendong-Su-group property-based Android-DME fuzzer journal extension) all carried 2026-06-23 03:02 UTC timestamps and were already covered in the [2026-06-24 digest](#). Nothing new has arrived since.

The preference posterior pipeline still ran: feedback pull found no open issues and the rebuild rewrote 19 attribute posteriors, with `venue::preprint` (0.75, $n = 2$) currently the only $n \geq 2$ prior. The empty result is a genuine lull, not a connector failure — a control probe against `from:scholaralerts-noreply@google.com` without a date filter returned 201 historical threads.

Outstanding: 0 · **Keep:** 0 · **Borderline High-Priority:** 0

Highlighted Papers

No new papers reached Stage-2 deep-read today.

Cross-Paper Synthesis

Not applicable — no Stage-2 cohort to synthesise across. The next digest will resume the standard format once new alerts arrive.

Writing & Rationale Insights

A null-day is itself useful signal: it confirms that the scheduled task survives an empty inbox without producing fabricated content. Three operational invariants were exercised: (i) Stage-1 author-level exclusion remains armed, (ii) STEP 2b parallel self-email channel is wired and returned 0 cleanly, and (iii)

preference posteriors are refreshed even when no candidates are scored against them, so tomorrow's run starts from the latest n-of-history rather than a stale snapshot.
